EE5903 RTS Chapter 4 Real Time Scheduling Policies

Bharadwaj Veeravalli

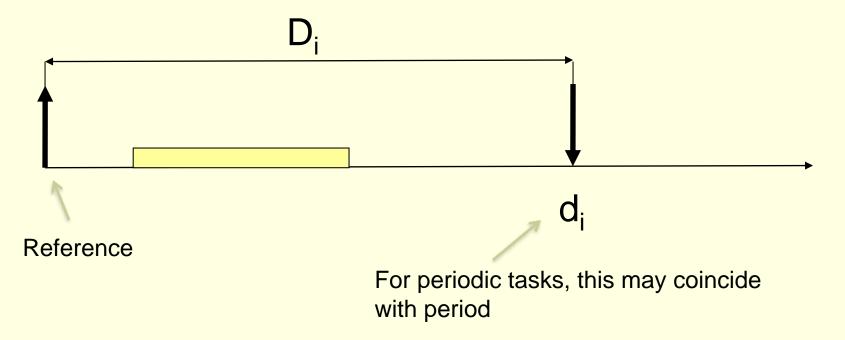

elebv@nus.edu.sg

Outline of this Chapter

- RT Scheduling Algorithms
 - -- EDD, EDF, LLF
- Non-Preemptive Scheduling
- Time-Triggered Systems
- Scheduling Anomalies Priority, # of CPUs, task sizes, resource constraints, etc
- Handling Overloaded Conditions
- Imprecise task scheduling strategies (uniprocessor)
- Handling Periodic Tasks with EDF, RMA and DMA
- Quick note on Event Driven Schedulers
- Precedence Constraints Static Scheduling algorithm
- Soft-real time issues (if time permits...)

Real-Time Aperiodic/Periodic Scheduling Algorithms

- Tasks can be scheduled by
 - relative deadlines D_i (static)
 - absolute deadlines d_i (dynamic)

RT Scheduling algorithms

- Earliest Due Date (EDD)
- Earliest Deadline First (EDF)
- Least Laxity First (LLF)
- Rate Monotonic Algorithm (RMA)

Classification of Scheduling Problems – Notational ease!

 α / β / γ [Graham et. Al 1979]

machine infrastructure / task information / metric

Classification Examples

Example 1:

$$\alpha / \beta / \gamma$$
: 1 / prec / L_{max}

Denotes the problem of scheduling a set of tasks with precedence constraints on a uniprocessor machine in order to minimize the maximum lateness.

If no additional constraints are indicated in the second field, preemption is allowed at any time, and tasks can have arbitrary arrivals.

Classification

Example 2:

$$\alpha$$
 / β / γ : 3 / no-preem / Σf_i

Denotes the problem of scheduling a set of tasks on a threeprocessor machine. Preemption is not allowed and the objective is to minimize the sum of the finishing times. Since no other constraints are indicated in the second field, tasks do not have precedence nor resource constraints but have arbitrary arrival times.

Classification

Example 3:

$$\alpha / \beta / \gamma$$
: 2 / sync / Σ Late_i

Denotes the problem of scheduling a set of tasks on a two processor machine. Tasks have synchronous arrival times and do not have other constraints.

The objective is to minimize the number of late tasks.

Earliest Due Date (EDD): 1 /synch / L_{max}

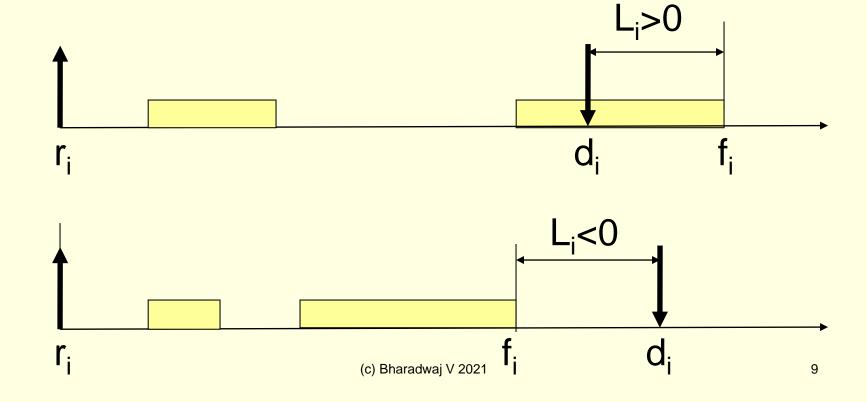

- It selects the task with the <u>earliest</u> relative deadline [Jackson's Algorithm].
 - All tasks arrive simultaneously
 - Fixed priority (D_i is known in advance)
 - Preemption is not an issue (why?)
 - It minimizes the maximum lateness (L_{max})

Theorem -- (Jackson's rule) Given a set of n independent tasks, any algorithm that executes the tasks in order of nondecreasing deadlines is optimal with respect to minimizing the maximum lateness.

EDD (Cont'd)...

Lateness:

$$L_i = f_i - d_i$$

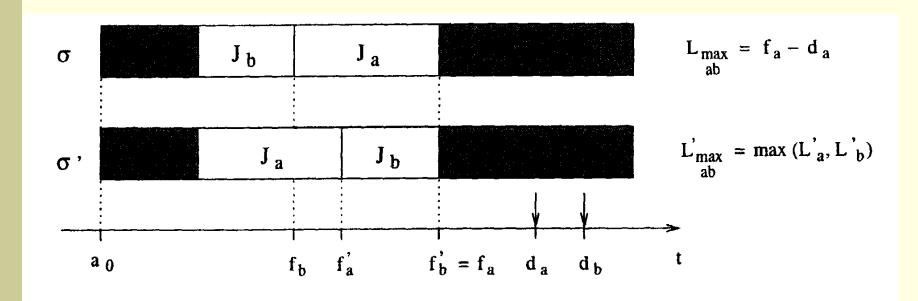

EDD (Cont'd)...

Maximum Lateness:
$$L_{max}=max_i(L_i)$$

if (L_{max} < 0) then no task misses its deadline

How do we prove Jackson's rule? We will use a simple interchange logic and applying this logic until optimal schedule is reached.

EDD Optimality – swapping argument

if
$$(L'_a \ge L'_b)$$
 then $L'_{max} = f'_a - d_a < f_a - d_a$ in both cases: $L'_{max} < L_{max}$ if $(L'_a \le L'_b)$ then $L'_{max} = f'_b - d_b < f_a - d_a$

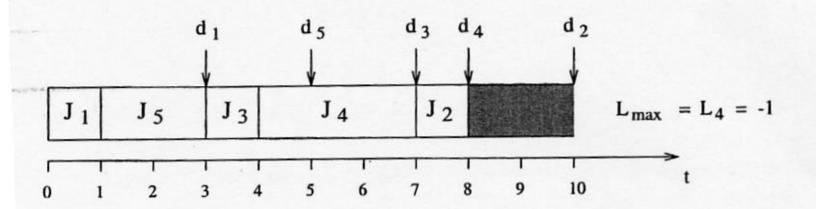

In the first case - (since $f'_a < f_a$)

In the second case: $f_b' = f_a$ and $d_b > d_a$

EDD – Example 1

	J ₁	J ₂	J 3	J 4	J 5
Ci	1	1	1	3	2
d _i	3	10	7	8	5

Note: Under EDD – All tasks arrive simultaneously

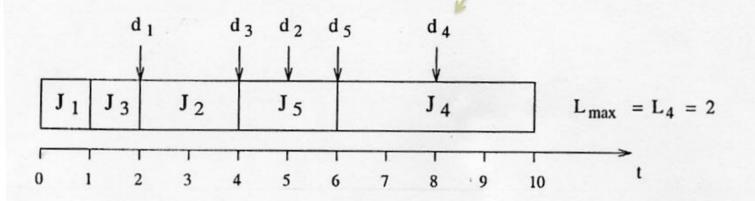

A feasible schedule produced by Jackson's algorithm.

EDD Example 2

	J 1	J 2	J 3	J 4	J 5
C_i	1	2	1	4	2
d i	2	5	4	8	6

This is an example wherein we demonstrate that EDD can result in an infeasible schedule

An infeasible schedule produced by Jackson's algorithm.

EDD - Guaranteed feasibility

Important Note: The optimality claim of the EDD algorithm cannot guarantee the feasibility of the schedule for any task set.

It only guarantees that if a feasible schedule exists for a task set, then EDD will find it. (Our Example 2 demonstrated this!)

Order tasks by increasing deadlines. Then:

$$\forall i=1,\ldots,n \quad f_i \leq d_i$$
 This implies, $f_i = \sum_{k=1}^i C_k$

Which implies,
$$\forall i=1,\ldots,n$$
 $\sum_{k=1}^{i} C_k \leq d_i$

EDD Optimality

Replace tasks one-byone to move earlier deadlines earlier

$$\sigma \longrightarrow \sigma' \longrightarrow \sigma'' \longrightarrow \sigma^*$$

$$L_{\max}(\sigma) \ge L_{\max}(\sigma') \ge L_{\max}(\sigma'') \dots \ge L_{\max}(\sigma^*)$$

$$\sigma^* = \sigma_{EDD}$$

 $L_{
m max}(\sigma_{EDD})$ is the minimum value achievable by any algorithm

Earliest Deadline First (EDF):

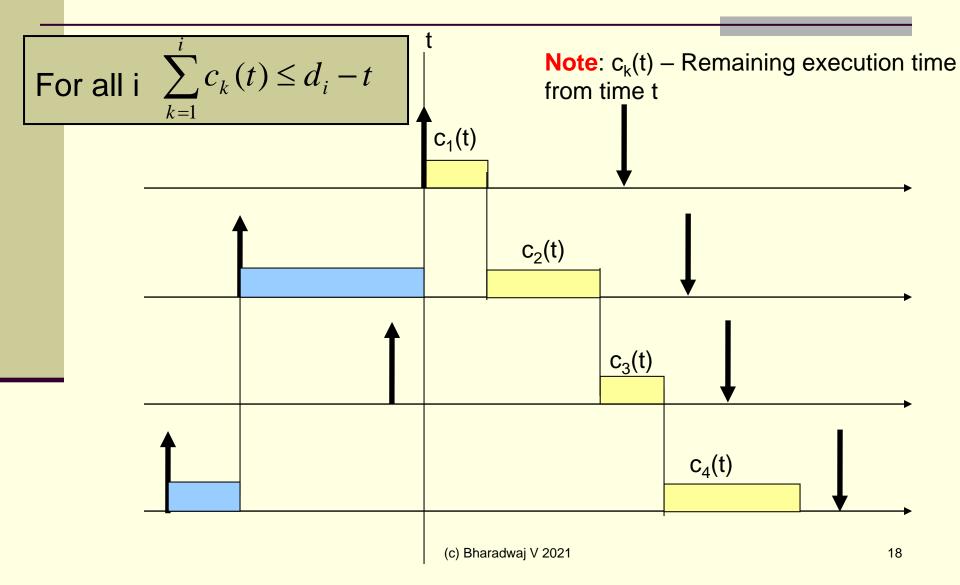

1 /preem/ L_{max}

- It selects the task with the earliest absolute deadline [Horn's Algorithm].
 - Tasks may arrive at any time
 - Dynamic priority (d_i depends on arrival)
 - Fully preemptive tasks
 - It minimizes the maximum lateness (L_{max})
- Newly arrived task is inserted into a queue of ready tasks, sorted by their absolute deadlines. Task at head of queue is executed.
- If a newly arrived task is inserted at the head of the queue, the currently executing task is preempted.

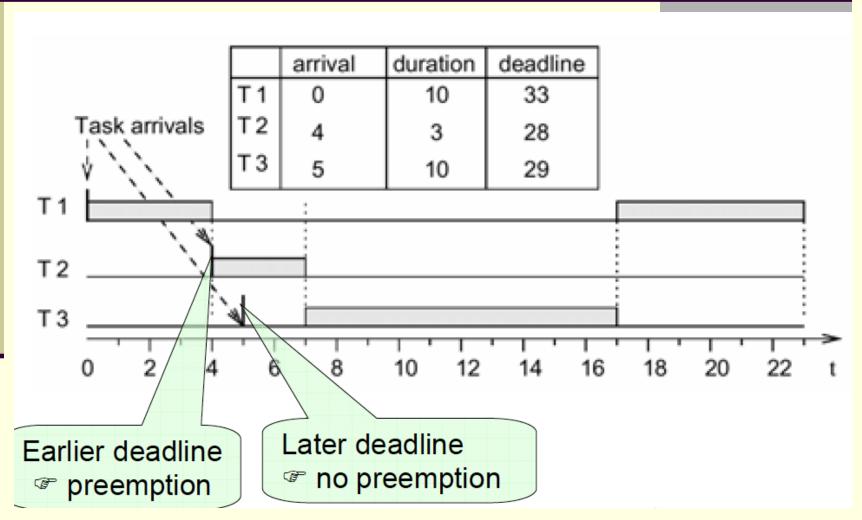

EDF Example

EDF Guarantee test (online)

EDF - Example

EDF for tasks with Equal Ready Times

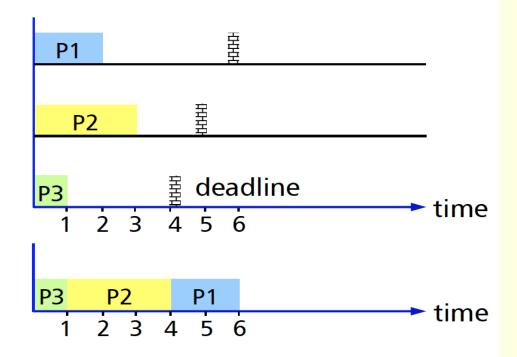

Static EDF with Equal Ready Times

- Sort processes with ascending deadlines [Jackson]
- Whenever a process is scheduled, check if its deadline is met or violated
- For the k-th process it must hold that

$$\sum_{i=1}^k C_i \le D_k \quad k = 1 \cdots n$$

EDF Optimality for Identical Ready Times: Single CPU

Example

EDF is optimal for identical ready times!

Proof of Optimality

- Proof (indirect)
 - The processor is always utilized
 - If the schedule has been timely before adding P_k , it is not any more afterwards: \underline{k}

$$\sum_{i=1} C_i > D_k$$

- ▶ The only possibility is then to exchange P_k with one of the already planned processes P_i (j < k)
- The sum of execution times remains unchanged
- $\blacktriangleright \ \, \text{We know that} \quad \, D_j \leq D_k \ \, \text{and thus}$

$$\sum_{i=1}^k C_i > D_j$$

- Therefore the exchange makes things worse
- Thus: If this algorithm does not find a solution, there is none

EDF Properties

- EDF is optimal for a uniprocessor schedule under pre-emption;
 - If there exists a feasible schedule then EDF will schedule the tasks

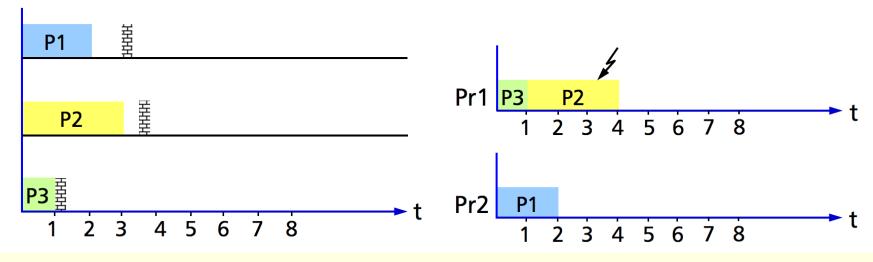

EDF achieves 100% processor utilization – If under EDF a deadline is missed then this means system is overloaded.

EDF on Multiprocessors - Example

What About Multi Processor Systems?

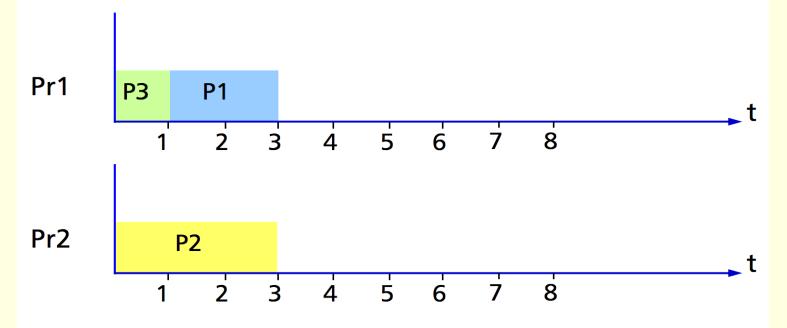

An example shows that EDF is not optimal even for the simple case of equal ready times

Tasks

EDF on MPS

► There is a timely schedule: (not following EDF!)
